

ESH Assumptions

ESH (Estimated Shoppers per Hour) is a Hannaford To-Go specific measure that estimates how many shoppers are available to work during each hour of the day.

It is calculated by taking the **total number of scheduled labor hours in that hour** and subtracting the value you enter in **ESH Assumptions**. This adjustment lets you account for non-shopping roles (like Expeditors) and breaks that reduce the number of active shoppers.

Example:

Suppose between 10:00 AM and 11:00 AM there are 4 people scheduled. One additional person's shift ends at 10:30, which contributes 0.5 hours, so the total scheduled time for that hour is **4.5 hours**.

If your department usually has 2 Expeditors and about 30 minutes of breaks during that time, you would enter **2.5** into ESH Assumptions for that hour.

The program then calculates:

```
Total scheduled hours:    4.5
Minus ESH assumption:    -2.5
-----
ESH value:                2.0
```

This number (2.0) represents the estimated active shoppers during that hour.

Why it's useful:

- Lets you quickly see where staffing may fall short or exceed expectations.
- Provides a comparison point against labor estimates from the OMS dashboard.
- Helps highlight gaps or surpluses in coverage at a glance.
